- 4. Set Up Email Notifications 4

1. Alert System Overview

The Alert System provides real-time monitoring and notification capabilities for portfolio risk events. It integrates with the Risk Engine to detect threshold breaches, compliance violations, and market anomalies. The system supports multiple notification channels, i.e., email, SMS, and in-app alerts.

Alerts are categorized by severity: Critical, Warning, and Informational. Each alert type can be configured with custom thresholds, escalation paths, and acknowledgement requirements, etc.

2. Configure Alert Rules

Alert rules define the conditions that trigger notifications. Each rule specifies a data source, a condition expression, and one or more actions to execute when the condition is met.

3. Alert Priority Settings

Setting	Code	Description
Priority Level	PRI	Sets the alert severity: Critical, Warning, or Info
Threshold Type	THR	Specifies absolute value or percentage-based threshold
Cooldown Period	CDN	Minimum time between repeated alerts (in minutes)
Escalation Path	ESC	Defines the chain of recipients for unacknowledged alerts
Auto-Resolve	ARS	Automatically close alert when condition returns to normal

4. Set Up Email Notifications

When you configure email notifications, you must specify the SMTP settings and recipient list for each alert priority level. You can use the Notification Manager panel to set up email notifications.

Before you begin, ensure you have SMTP server credentials and admin access.

To set up email notifications:

1. In the Admin Console, select Settings > Notifications > Email Setup.
2. Enter the SMTP server address and port number.
3. Click Test Connection to verify the SMTP settings.
4. In the Recipients panel, add email addresses for each priority level.
5. Click Save to apply the notification settings.

After you save the notification settings, the system sends a confirmation email to all configured recipients.

```
# Example: Custom alert filter script
def filter_alerts(alerts, min_priority="Warning"):
    levels = {"Info": 0, "Warning": 1, "Critical": 2}
    threshold = levels.get(min_priority, 0)
    return [a for a in alerts if levels.get(a.priority, 0) >= threshold]
```
